## Transporting Configuration Between Servers Online Training

### Abstract:

This training will give you a basic understanding of Global Process Manager (GPM). You will learn how to create, load, and deploy packages from one DELMIA Apriso system to another.

### Detailed objectives. After the training you will:

- ▶ How to install Global Process Manager
- ▶ How to create projects and add elements to them
- ▶ How to transfer packages between multiple servers

### Target audience:

- ▶ People who will need to work on DELMIA Apriso solutions on multiple servers

### Requirements:

- ▶ Working knowledge of Process Builder

### Role and level:

- ▶ People who will be working configuring DELMIA Apriso

Duration: 60 min

## Chapter 1: Overview of Global Process Manager

In this chapter you will find out what Global Process Manager (GPM) is, how to install it, and will guide you through the main GPM user interface features.

### Here are the chapters to be covered:

1. Overview of Global Process Manager
2. Creating and Deploying Packages

## What is Global Process Manager

Global Process Manager (GPM) is a tool developed to deploy DELMIA Apriso solutions, regardless of their customization level or location.

Deployment is now fast, manageable, and reliable, with support for single and multi-server production environments.

This application allows you to create configuration packages, save them locally or in a desired network destination, and load them on different servers.

Only one instance of GPM is needed - but it can service multiple destination servers that can be manually added.

## Menu Bar

- 1 The **Menu Bar** consists of four menus: File, View, Action, and Help
  - **File** - contains the Options and Exit command
  - **View** - lets you set the view options for the current View Pane. The view settings are remembered for each View Pane. This menu also allows the user to toggle the visibility of the In-Project Folders and to group by export status
  - **Action** - commands differ for each View Pane currently active. This gathers all of the commands from the right-click menus. Note that some commands can only be executed under certain conditions (e.g., an item must be selected). This menu may also include additional actions not available in the right-click menu
  - **Help** - provides access to this Help, allows the display of the Welcome Screen (useful for users who want to learn about changes in the newest version) as well as important console information (About)

## Chapter 2: Creating and Deploying Packages

In this chapter you will learn what packages are, and how you can transport DELMIA Apriso configuration between servers using packages. You will also have a chance to create your own package, and to load and deploy another package on the training server.

### Here are the chapters to be covered:

LAB 2: Create New Folder

LAB 2: Create a Project

## GPM Projects

A **GPM Project** is used to group entities in GPM, including operations, users, database tables, etc. which are related to one piece of a functionality.

- ▶ All needed objects are linked to a GPM Project
- ▶ Then, a package can be generated from the GPM Project. It contains a snapshot of data based on the content list of this project
  - ❑ Packages are used to transfer data
- ▶ When new package is generated - it gets new build number. This way you can easily manage your deployment by looking at the latest deployed package build number

GPM Folders

GPM Packages

Modes of Package Generation

Packaging Entities

GPM Folders vs. Projects vs. Packages

LAB 2: Create Package

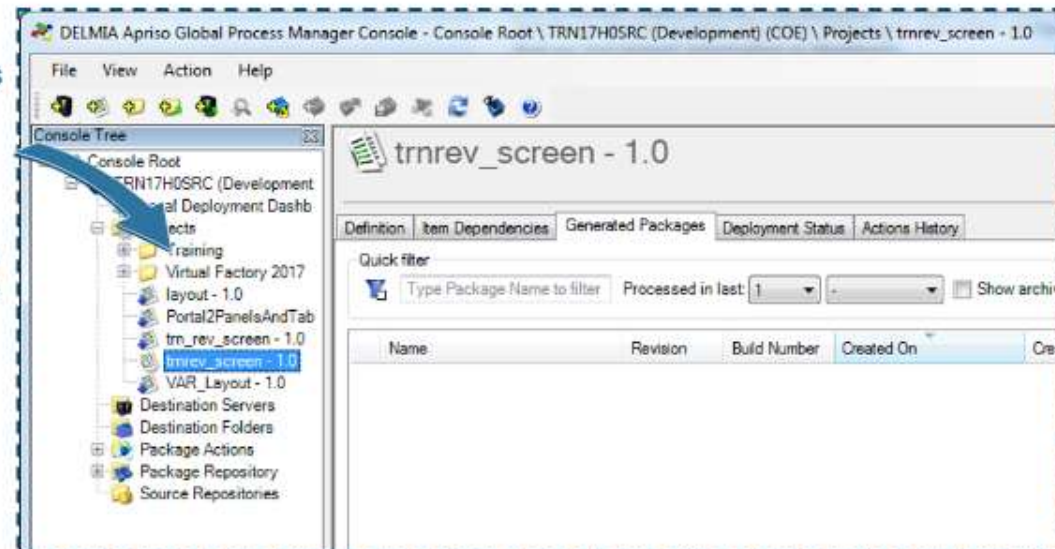

LAB 2: Create Package

LAB 2: Create New Folder

LAB 2: Create a Project

## GPM Folders

- ▶ GPM Projects can be grouped by **folders**
- ▶ In DELMIA Apriso projects, a lot of configuration is transported first from development server to test server, and then to the production server. Also, when deploying the DELMIA Apriso solution to further plants, GPM is used, too
- ▶ This is why it is extremely important that the GPM folders are used to create a folder structure which clearly and completely describes all elements which need to be transported to other servers for the solution to work on destination servers

## GPM Packages

A **package** is a file with a snapshot of objects listed in the GPM Project

- ▶ Generated based on all or subset of elements in the Project
- ▶ Every package gets a new build number
- ▶ Build number are used by the system to make sure the packages are deployed on destination server in the right sequence
- ▶ Usually, the very first package from a project will include all configuration, and the subsequent packages will have only the changes to any objects which were done on the server since the time the previous package was generated

Training	1.0	1	12/13/2013 2:19:42 PM	ADMIN

## Modes of Package Generation

There are three different ways to create a package. Read the below to find out more about each way:

- ▶ **Cumulative** - all items in the project are added to the generated package. It is not possible to generate a cumulative package if any of the items in the project has an invalid status (Missing, In Design, Cancelled)
- ▶ **Differential** - only items modified/added since the last generation of the package are added to the generated package (the system automatically detects changes before generating). Dependency is automatically added to the package previously generated from this Project
- ▶ **From Selection** - only the selected items are added to the generated package. A dependency is automatically added to the package previously generated from this project. If there are items in statuses Missing, Cancelled, In Design, Ignored then the package cannot be generated and an error message will appear

Objects in Design in Progress status will never be packaged by GPM. They need to be in Prototype or Active status

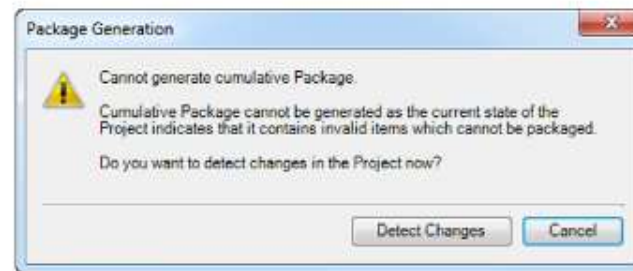

## Packaging Entities

When adding Entities to the package, remember that only Entities in Active or Prototype status can be packaged.

If any of the added Entities is in another status, an error message will appear and inform you about it.

You can easily go back to Process Builder, change the statuses of all the Entities that are not in Active or Prototype, and add those files to packages again.

## GPM Folders vs. Projects vs. Packages

In the example here, the top node in the **folder** structure is Realization Phase (which is derived from DELMIA Apriso project methodology), then you have a folder with customer name, and then with project phase (MES.I.001).

The Global projects folder will contain folders with complete definitions of respective functionalities, e.g. Production will contain all Scrap Management configuration, and Scrap\_Management\_SC-10 will contain all configuration for the SC-10 functionality as defined in the design documents.

GPM Projects are created at the lowest level of Folders. A **project** needs to include all configuration elements related to the given functionality.

When **packages** are generated, you can see their lists in the Generated Packages tab under projects.

These packages are available on the server, and they can be saved as files (with .gpm extension), or deployed to other servers directly.

LAB 2: Add Item Command, part 2

LAB 2: Generate a Cumulative  
Package

LAB 2: Check the Package Status

LAB 2: Save the Package to a  
Folder, part 1

## LAB 2: Create New Folder

- ▶ Open GPM by double-click on the desktop icon
- ▶ If not yet connected, right-click on the server name, choose Connect and provide your account details to connect

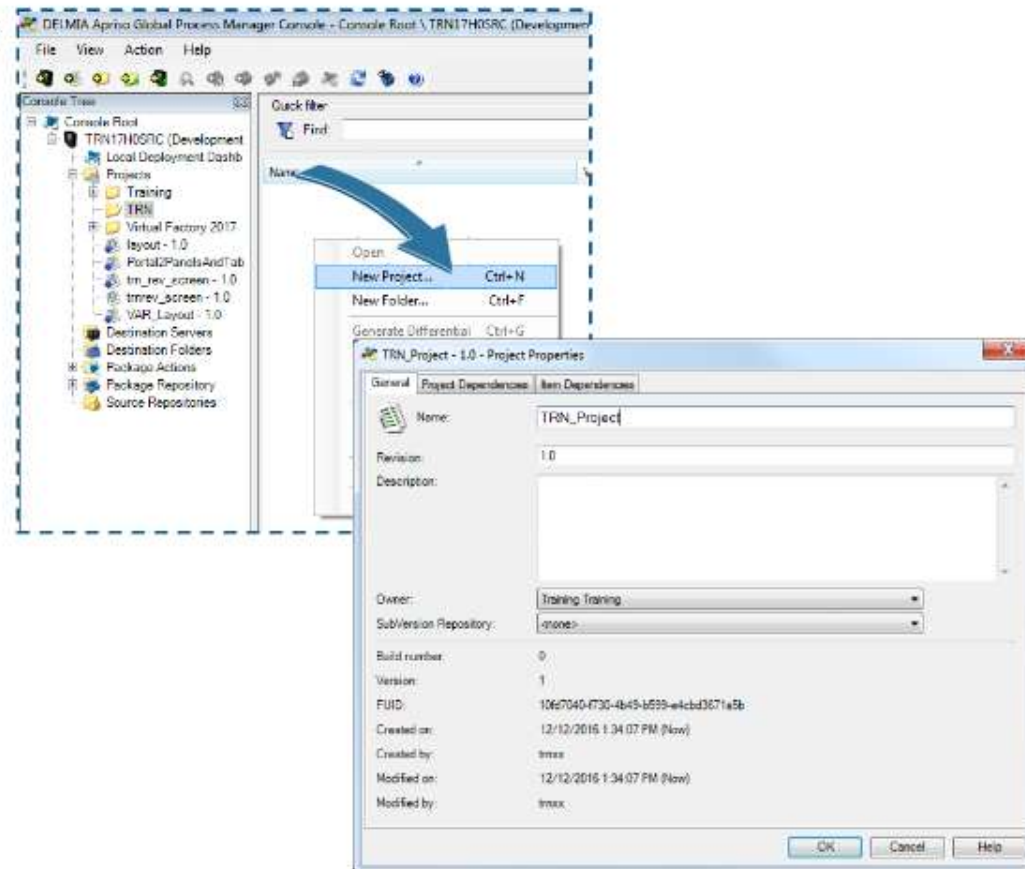

- ▶ Click on your training server node (the level under Console Root)
- ▶ Right-click on Projects
- ▶ Choose New Folder
- ▶ Name the folder **TRNXX**

## LAB 2: Create a Project

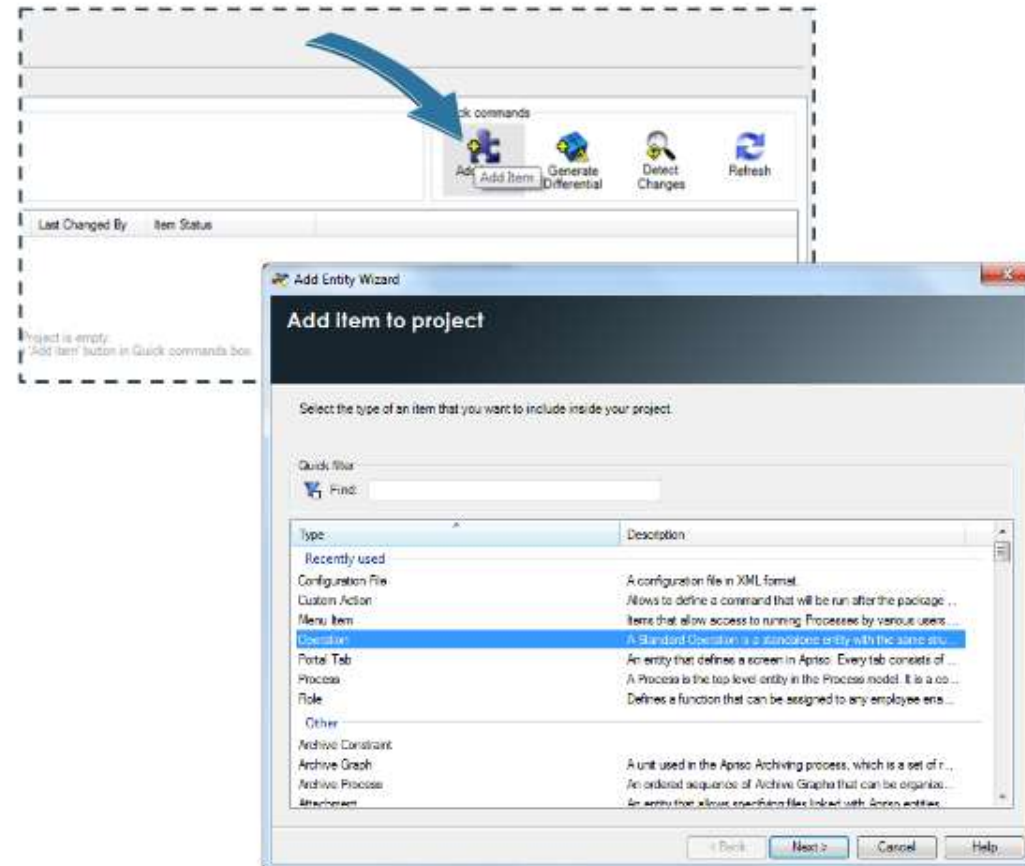

- ▶ The system will automatically open the new folder
- ▶ In the folder, right-click to create a new project
- ▶ Name the project **TRNXX\_Project**

## LAB 2: Add Item Command, part 1

- ▶ Add project files to the project using Add Item button
- ▶ When you click on the button, the Add Entity Wizard will open
- ▶ Choose **Operation** from the list of available entities

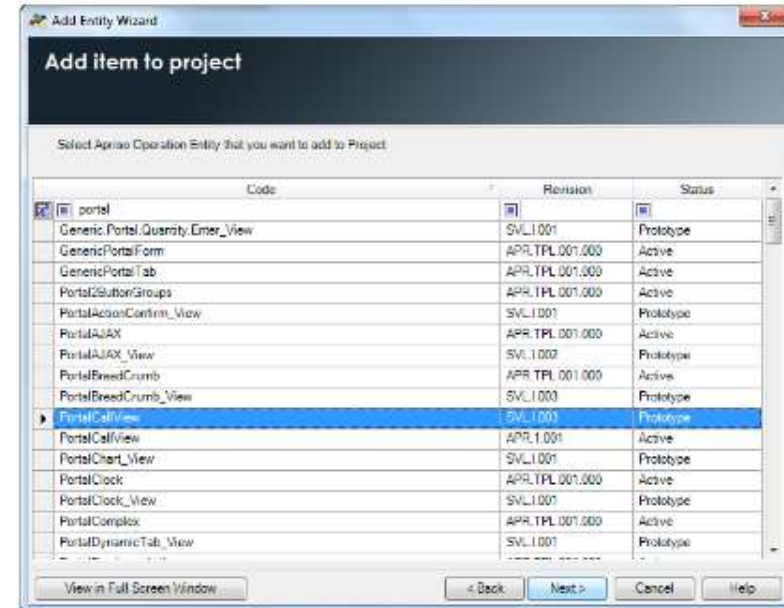

## LAB 2: Add Item Command, part 2

- ▶ In the list of Operation, type portal to narrow the search for any portal-related Operations
- ▶ Choose the **PortalCallView** Operation, Revision **APR.1.001**, and click Next
- ▶ On the comment screen, click Finish

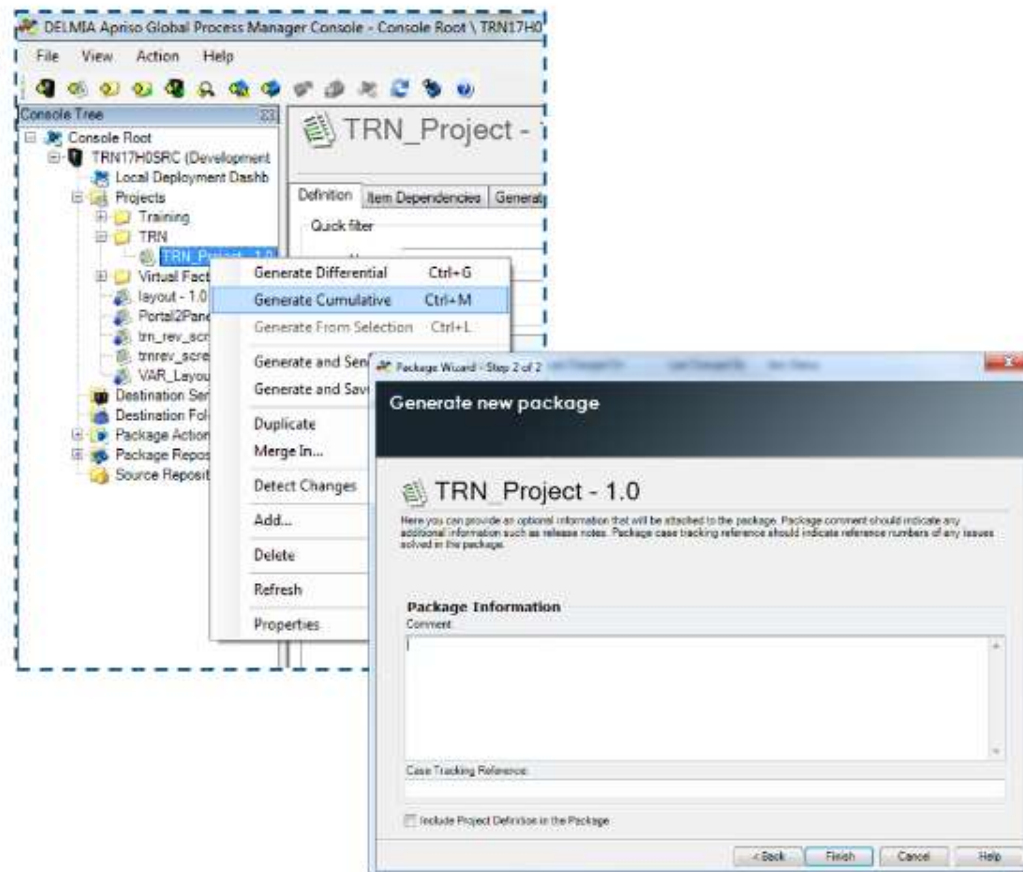

- ▶ When the processing is finished, you should see the PortalCallView Operation in your project.

## LAB 2: Generate a Cumulative Package

- ▶ Generate a cumulative package, by choosing the appropriate option from the right-click menu in the Console Tree where your project should be selected
- ▶ Click Next on the first screen of Package Wizard
- ▶ Click Finish on the second screen of Package Wizard

## LAB 2: Check the Package Status

- ▶ You will see the package is being generated - it also says who initiated the package
- ▶ When the operation is finished, the package is marked as Packaged
  - Right-click on Refresh (or use F5) after few seconds to make sure the screen displays the latest stage of the package

You are now ready to save the package so it can later be sent to another server.

## LAB 3: Package Repository

- ▶ The package will appear on the list in Package Repository

- ▶ The Package Repository will usually have very many packages received, loaded, or generated on the server
- ▶ You may want to look for your package in the Loaded folder, to browse through a smaller number of packages

## LAB 3: Deploy the Package

- ▶ While still in the Package Repository, right-click on the package and choose Deploy...
- ▶ Don't change any deployment options, and click OK

- ▶ When the deployment is finished, you will see a popup at the bottom of the screen. You can click on the icon to see more information

- ▶ After the deployment, go to Projects and see if you can find the project named GPM001 Training.
- ▶ It will contain the information about generated and deployed packages

When a deployment is successful, it means that the objects from the package were placed in appropriate locations on the server.
